

React Forms

Controlled vs. Uncontrolled Form Fields

In React, form fields are considered either *uncontrolled*, meaning they maintain their own state, or *controlled*, meaning that some parent maintains their state and passes it to them to display. Usually, the form fields will be controlled. The example code shows an uncontrolled and controlled input.

```
const uncontrolledInput = <input />;

const controlledInput = (
  <input value={stateValue} onChange={handleInputChange}
/>
);
```

Controlled Components

A controlled form element in React is built with a change handler function and a `value` attribute.

```
const controlledInput = (
  <input value={stateValue} onChange={handleInputChange}
/>
);
```
